

C Methodological and biological synthesis

Consensus biological conclusions

- Early Wnt precedes acquisition of epiblast competence.
- Control gastruloids progress through primitive streak toward caudal mesoderm / NMP / PSM / somite trajectories.
- Early-treated gastruloids accumulate ectopic pluripotency and show impaired somitogenic progression.
- Spatial organization is likely less coordinated in early-treated structures.
- Control gastruloids show greater biological variability.

Deconvolution-algorithm agreement

Possible explanation: weighted least squares and marker-weighting may be more sensitive to collinearity among closely related cell states, causing stronger penalization/down-weighting of correlated genes and less stable absolute abundances.

Use robust consensus across methods for biology:
ectopic pluripotency ↑, primitive streak ↓, PSM ↓, control variability ↑.
